

eSIMManager 2.0: what changed

Install comes first

The card detail screen was reorganized: "Start installing eSIM" now sits right at the top - no more scrolling to find it. Secondary info (basic details, usage period, plan data, and more) is collapsed by default and expands only when you need it.

Two new safety nets

A self-correction alert now appears if your local usage estimate exceeds the plan's total, so it doesn't just look broken. A new cleanup checklist also appears after a trip ends, helping you decide whether to remove a used-up eSIM in system settings.

About these examples

This guide uses the Tabi light appearance to demonstrate 2.0. Screens are from the simulator with fictitious cards and no real activation credentials. Wa, Komorebi and dark mode offer the same functions with different layouts.

Quick install in three steps

① Start installing eSIM

Open a card's detail screen and the first thing you see is the "Start installing eSIM" button, marked with a numbered ① badge. It only appears when the card has a complete SM-DP+ address and activation code. Tapping it opens a confirmation, then either the Settings app or an in-app system installation screen.

② Mark as active

Right below it is "Mark as active" (badge ②) - the natural next step once installation is done. This only updates the app's own record; it does not complete system installation for you, and it does not activate or switch your iPhone's cellular data line.

Why the order matters

Numbering these two actions responds directly to feedback that the old install trigger sat at the very bottom of the page under an unclear label. They're now ordered to match the actual install sequence, so there's nothing to hunt for.

Full install: from QR to system confirmation

When there's no quick-install button

If a card is missing complete activation data (for example, restored from a backup that excludes sensitive details), "Start installing eSIM" won't appear. Use the provider's own QR code, their official app, or Apple's instructions instead, and fill in the missing details on the Edit screen.

What happens after you tap install

A confirmation ("Proceed with installation?") appears first. Continuing on iOS 17.5+ opens the Settings app's system install screen; on iOS 17.4 the same system screen appears inside this app instead. Either way, you must confirm manually in the system UI - the app cannot finish this for you.

If installation fails

If the system reports it can't open the installation flow, check your network connection and use the provider's QR code or official app instead of repeatedly deleting and reinstalling the card.

Share or install for someone else

Two kinds of sharing, two purposes

"Share eSIM record and activation details" is for another device that already has this app - the recipient imports a record. "Export a family/companion install card" is for someone with no app installed at all, letting them scan it directly with their iPhone's Camera app.

Single device, single use

A caption right next to the install-card button says exactly that: "For one device, one installation only - not a reusable general-purpose link." Most carrier activation codes only ever succeed once, so confirm this card is meant for that specific person before sharing, not one already used elsewhere.

Sharing doesn't touch your own card

Neither sharing method deletes your original card record or changes your iPhone's system settings. Whether the other person can actually install it still depends on the provider's rules and whether that code has already been used.

Pre-departure setup guide: three stages at a glance

A quick-glance overview card

The pre-departure setup guide now includes an at-a-glance "iPhone settings overview" card summarizing what to do with cellular data, Allow Cellular Data Switching, and your primary/secondary lines - shown persistently above the stage switcher.

Three stages

Before departure, confirm install timing and protect your primary line. On arrival, select the travel eSIM for cellular data in system settings and test the connection before checking items off. On return, switch back to your usual line and verify calls and data work.

The guide only records your checkmarks

Each stage's progress is saved separately, but the guide itself cannot read or directly change your iPhone's actual cellular settings, and it cannot guarantee you'll avoid roaming charges entirely - the real settings still need your own confirmation in the system UI.

Usage over-limit alert and trip cleanup

New: an over-limit self-correction alert

Local usage estimates work by totaling traffic on the device's cellular interfaces. If you forget to stop tracking the old card before switching eSIMs, the number can keep climbing past your plan's total. 2.0 now detects this and offers a "Recalibrate" option that resets the estimate to zero and starts over.

Still just an estimate

This alert is a purely local convenience feature. It is not your carrier's real-time bill, and it cannot identify which eSIM actually carried the traffic. Always rely on your carrier or purchase platform for real usage and billing.

New: a trip-cleanup checklist

After a trip ends, the card detail screen shows a cleanup card with two confirmation items (the trip has actually ended; this isn't your primary line) plus a shortcut button straight into system Cellular settings, helping you decide whether to remove a used-up eSIM yourself. The app cannot read or delete a system eSIM directly - that decision stays with you.
